### Data Structures & Programmatic Thinking

#### Plan for this session

• Learn about dictionaries

#### **Dictionaries**

Dictionaries are another kind of collection in Python. Dictionaries map keys to values.

### Creating dictionaries

We use curly brackets  $(\{\})$  to declare dictionaries.

```
translations = {
    "es": "Hola!",
    "it": "Ciao!",
    "en": "Hello!"
}
```

colon for separating key and value comma for separating entries

### Creating dictionaries

We can also create empty dictionaries

translations = {}

# Creating dictionaries

#### Adding elements

We add elements to dictionaries given their specific index:

```
translations = {}
translations["en"] = "Hello"
translations["it"] = "Ciao"
translations["es"] = "Hola"
```

# Adding elements

#### Updating elements

we always can change a value in the dictionary by re-assigning the key

```
translations = {}
translations["en"] = "Hello"
translations["en"] = "WHATUP!"
```

# Updating elements

#### Deleting elements

We can delete an element of the dictionary using the **pop** method

```
translations = {}
translations["en"] = "Hello"
translations.pop("en")
```

# Deleting elements

#### Getting all keys or values

We can allways get all **keys** or **values** from the dict as a list using either the .keys() or .values() method

```
users = {
    1: "Pepe",
    22: "Peter",
    44143: "Johnny",
    2: "Chuck"
}
users.keys()
users.values()
```

# Getting all keys or values

#### for loops

In the same way we used **for** loops to iterate over elements of a list, we can use them to iterate over elements of a dictionary.

The difference is that, with dictionaries, the **iteration variable** will represent the **current key**, not the **current value**.

### for loops

```
band = {
   "johnny": "plays drums",
   "joey": "plays guitar",
   "markee": "sings",
   "dee-dee": "plays bass-guitar"
}

for member in band:
   print(member + " " + band[member] + " in The Ramones")
```

# for loops

#### **Exercises**

- Create a function that receives a text and returns the frequency of each word in the text (as a dictionary).
- Create a function that uses the previously generated dictionary and prints a bars diagram of the frequencies. For example, the following:

```
dictionary = {"a": 4, "hello": 1, "world": 3, "another": 2}
diagram(dictionary)
```

should print:

```
a | ****
hello | *
world | ***
another | **
```
